# Intuition: Margins

## ■ Separating Hyperplane

- Our confidence about the prediction of classes of A, B and C relies on their distance from decision boundary.
- We try to find the optimal hyperplane that separates the classes in the feature space.

# Hyperplane

- **Hyperplane:** A hyperplane in  $p$  dimensions is a flat affine subspace of dimension  $p-1$ :

$$\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p = 0$$

- The vector  $\beta = (\beta_1, \beta_2, \dots, \beta_p)$  is called the normal vector – it points in a direction orthogonal to the surface of the defined hyperplane.
- If  $f(X) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p = \beta^T X + \beta_0$ , then  $f(X)$  divides the  $p$ -dimensional feature space into two half-spaces ( $f(X) > 0$  for one side and  $f(X) < 0$  for the other side).
- So if we code  $Y^{(i)} \in \{\pm 1\}$ , then  $\forall i$

$$Y^{(i)} f(X^{(i)}) > 0$$

# Maximal Margin Classifier

- **Maximal(Optimal) Separating Hyperplane:** The separating hyperplane with the biggest margin between the classes.

$$\begin{aligned}
 & \max_{\beta_0, \beta, M} \quad M \\
 & \text{s.t.} \quad \sum_{j=1}^p \beta_j^2 \\
 & \quad y^{(i)}(\beta^T x^{(i)} + \beta_0) \geq M \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned} \tag{1}$$

# Maximal Margin Classifier: Quadratic Program

- Eq.(1) can be rephrased as a convex quadratic problem and be solved efficiently using QP solvers.
- (Euclidean) distance between two hyperplanes

$$\mathcal{H}_1 = \{x | \beta^T x + \beta_0 = 1\} \quad \mathcal{H}_2 = \{x | \beta^T x + \beta_0 = -1\}$$

is  $\text{dist}(\mathcal{H}_1, \mathcal{H}_2) = 2/\|\beta\|_2$

$$\begin{aligned} \min_{\beta, \beta_0} \quad & \frac{1}{2} \|\beta\|_2^2 \\ \text{s.t.} \quad & y^{(i)}(\beta^T x^{(i)} + \beta_0) \geq 1 \quad \forall i \in 1, 2, \dots, N \end{aligned} \quad (2)$$

# Non-linearly Separable Data

- In most cases however, the data are not linearly separable unless  $N < p$ .

# Noisy Data

- Sometimes the data are linearly separable, but noisy. This can lead to a poor solution for the maximal margin classifier. Also, hard-margin classifier is sensitive to outliers.

- The *support vector classifier* (SVC) maximizes a *soft* margin.

# Support Vector Classifier(Soft Margin Classifier)

- Allowing some samples to violate the margin, with *slack variables*, in a controlled manner:

$$\begin{aligned}
 & \min_{\beta, \beta_0, \xi} \quad \frac{1}{2} \|\beta\|_2^2 + C \sum_{i=1}^N \xi_i \\
 & \text{s.t.} \quad y^{(i)}(\beta^T x^{(i)} + \beta_0) \geq 1 - \xi_i \\
 & \quad \quad \xi_i \geq 0 \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned} \tag{3}$$

# Effect of Regularization Parameter

- $C$  is a regularization parameter that controls the bias-variance trade-off of the support vector classifier.

# The Need for Non-Linear Boundary

- Linear boundary can fail in many cases, regardless of the value of  $C$ .

# Feature Expansion

- Enlarge the space of features by including transformations; e.g.  $X_1^2, X_1^3, X_1 X_2, X_1 X_2^2, \dots$ . Hence increasing the dimension of the original  $p$ -dimensional input space.
- Then we can fit a support vector classifier in the enlarged space.
- This results in non-linear decision boundaries in the original feature space.

# Dual Problem of SVC

## ■ Primal problem:

$$\begin{aligned}
 \min_{\beta, \beta_0, \xi} \quad & \frac{1}{2} \|\beta\|_2^2 + C \sum_{i=1}^N \xi_i \\
 \text{s.t.} \quad & \mathbf{y}^{(i)} (\beta^T \mathbf{x}^{(i)} + \beta_0) \geq 1 - \xi_i \\
 & \xi_i \geq 0 \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned}$$

## ■ Dual problem (using the lagrangian):

$$\begin{aligned}
 \max_{\alpha_i} \quad & \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N \alpha_i \alpha_j \mathbf{y}^{(i)} \mathbf{y}^{(j)} \mathbf{x}^{(i)T} \mathbf{x}^{(j)} \\
 \text{s.t.} \quad & \sum_{i=1}^N \alpha_i \mathbf{y}^{(i)} = 0 \\
 & 0 \leq \alpha_i \leq C \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned} \tag{4}$$

# KKT Conditions

- From Karush-Kuhn-Tucker (KKT) conditions and complementary slackness we have:

$$\begin{aligned}\alpha_i(1 - \xi_i - y^{(i)}(\beta^T x^{(i)} + \beta_0)) &= 0 \\ (C - \alpha_i)\xi_i &= 0\end{aligned}$$

- There can be 3 cases:

$$\left\{ \begin{array}{ll} \alpha_i = 0 \rightarrow \xi_i = 0 \Rightarrow 1 - y^{(i)}(\beta^T x^{(i)} + \beta_0) < 0: & \text{Non-Support} \\ 0 < \alpha_i < C \rightarrow \xi_i = 0 \Rightarrow 1 - y^{(i)}(\beta^T x^{(i)} + \beta_0) = 0: & \text{Support} \\ \alpha_i = C \rightarrow \xi_i > 0 \Rightarrow 1 - \xi_i - y^{(i)}(\beta^T x^{(i)} + \beta_0) = 0: & \text{Support} \end{array} \right.$$

# Classification Function

■  $f(x) = \beta^T x + \beta_0$

■ Also, when minimizing the conjugate function of primal problem, we get:

$$\beta = \sum_{i=1}^N \alpha_i y^{(i)} x^{(i)}$$

■ This results in the following classification function for SVC:

$$f(x) = \beta_0 + \sum_{i=1}^N \alpha_i y^{(i)} x^T x^{(i)} = \beta_0 + \sum_{i=1}^N \alpha_i y^{(i)} \langle x, x^{(i)} \rangle \quad (5)$$

■ It turns out that most of the  $\hat{\alpha}_i$  can be zero:

$$f(x) = \beta_0 + \sum_{i \in \mathcal{S}} \hat{\alpha}_i y^{(i)} \langle x, x^{(i)} \rangle \quad (6)$$

where  $\mathcal{S}$  is the *support set* of indices  $i$  such that  $\hat{\alpha}_i > 0$ .

So, all we need is *inner products*!

# Kernels and SVMs

- Consider the feature mapping  $T : x \rightarrow \phi(x)$ , we define the corresponding *kernel* to be

$$K(x, x') = \langle \phi(x), \phi(x') \rangle.$$

Now we can simply replace all inner products by  $K(x, x')$ , and our algorithm would now be learning using the features  $\phi$ .

- Kernel matrix:  $K_{i,j} = K(x^{(i)}, x^{(j)})$

A valid kernel function is the one that results in a symmetric positive semi-definite kernel matrix for any set of samples. (Necessary and sufficient: Mercer theorem)

- Calculating kernel matrix may be very inexpensive, even though  $\phi(x)$  itself may be very expensive to calculate(perhaps because it is an extremely high dimensional vector).
- The classification function solution has the form

$$f(x) = \beta_0 + \sum_{i \in \mathcal{S}} \hat{\alpha}_i y^{(i)} K(x, x^{(i)}) \quad (7)$$

# Polynomial Kernels

$$K(x, y) = (1 + \langle x, y \rangle)^d \quad (8)$$

- e.g. Feature transformation from 2D kernels:

$$K(x, y) = (1 + \langle x, y \rangle)^2 \Rightarrow \phi(x) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, x_2^2)$$

- e.g. Polynomial kernel of degree 3:

# Radial Basis Kernels

$$K(x, y) = \exp(-\gamma \|x - y\|_2^2) \quad (9)$$

- $\gamma$  is the hyperparameter to be chosen to control the bias-variance trade-off.
- e.g. Radial basis functions (RBF) kernel:

# Multi-class SVM

- **One-vs-All:** Fit all  $K$  different 2-class SVM classifiers  $\hat{f}_k(x)$ ,  $\forall k \in 1, 2, \dots, K$ ; each class versus the rest. Classify  $x^*$  to the class for which  $\hat{f}_k(x)$  is the largest.
- **One-vs-One:** Fit all  $\binom{K}{2}$  pairwise classifiers  $\hat{f}_{kl}(x)$ . Classify  $x^*$  to the class that wins the most pairwise competitions.

(a) One-vs-All

(b) One-vs-One

# Support Vector Regression

$$\begin{aligned}
 \min_{\beta, \beta_0} \quad & \frac{1}{2} \|\beta\|_2^2 \\
 \text{s.t.} \quad & |y^{(i)} - (\beta^T x^{(i)} + \beta_0)|_2 \leq \epsilon \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned} \tag{10}$$

# Soft Support Vector Regression

$$\begin{aligned}
 \min_{\beta, \beta_0} \quad & \frac{1}{2} \|\beta\|_2^2 + C \sum_{i=1}^N \xi_i \\
 \text{s.t.} \quad & |y^{(i)} - (\beta^T x^{(i)} + \beta_0)|_2 \leq \epsilon + \xi_i \\
 & \xi_i \geq 0 \quad \forall i \in \{1, 2, \dots, N\}
 \end{aligned} \tag{11}$$

# Final Notes

**Thank You!**
